

Dry Socket Prevention - \$100

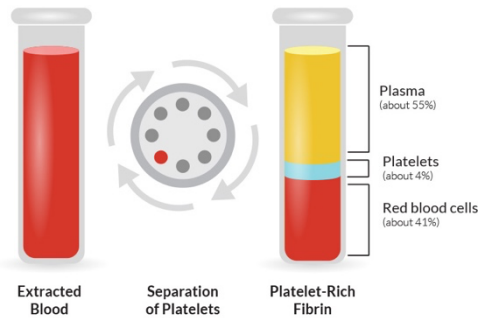

After surgery, the body sends **white blood cells** to the surgical area to begin the healing process.

This healing process takes several days, and also brings **pain, swelling and inflammation**.

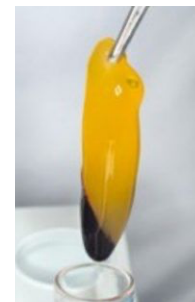

We can now collect these healing cells **ahead of time** from your own blood.

Your blood is drawn into a vial and used to create **Platelet Rich Fibrin**.

The Platelet Rich Fibrin clot is **placed into the extraction socket**.

The healing cells are now present immediately, giving you a **three-day head start** on the healing process.

PRF reduces pain, speeds healing, and lowers the chance of getting a dry socket.
